## Methodological Report American Jewish Population 2015: Political Orientation

## Elizabeth Tighe, Raquel Magidin de Kramer, Daniel Parmer

Nearly all of the surveys (255 of 257 surveys, n=283,000 respondents) in the current Jewish population data synthesis included questions about political orientation, in particular, party identification (Democrat/Republican) and views (Liberal/Conservative). Even among surveys that were on general topics of social issues, these two questions were included as background variables. Similar to our synthesis of data to estimate the Jewish population, data across these surveys were statistically combined to describe the distribution of party identification and political views within the Jewish population, as well as for the population overall.

For each of question (party identification and political views), three separate population models were run. The first two models were used to establish population "base rates" of the distributions of Democrats & Republicans (or Liberals & Conservatives), where population base rate is defined as the prevalence among all US adults, not just within the Jewish population. These models employed the same method as our Jewish population models, multilevel Bayesian regression models with poststratification. Geographic and demographic variables related to sampling were included as covariates. For political variables, unlike Jewish population models, there were more interactions among covariates that needed to be included. For example, there were significant interactions of race/ethnicity with age, sex and educational attainment. The results from these first two models were used to infer the base rates of the third category of outcome "Neither", that is, the remaining proportion of adults who identify with neither of the two major US political parties.

In addition to the two models used to establish base rates within the population as a whole, a third model was then run to describe the distribution of political party identification within the Jewish population. This was obtained by adding the party identification (Repub/Dem/Neither) to our standard Jewish population model.

Although there are no published statistics on the distribution of self-identified political party identification and political views for the geographic areas used in our models, the results from these data synthesis models yield similar distributions nationally as those observed and reported in other nationally representative samples (see Table 1).

The data synthesis yields an estimate of 36% of US adults identifying as Democrat, 25% as Republican and 39% identifying with neither party. This latter group includes those who identify as Independents, with no party, or with other particular parties such as Libertarian or the Green party. These estimates are similar to estimates currently reported on the Huffington Post Pollster, which estimates 36% Democrat, 29% Republican and 37% Independent or other identification. The Huffington Post Pollster estimates are based on a combination of data across 90 different polling organizations.

Also included in Table 1 are data from the American National Election Studies (ANES) and the General Social Survey (GSS) -- each pooled over the sets of years covered by the data synthesis. For the ANES this includes data from 2008 and 2012. For the GSS this includes data from 2008, 2010 and 2012. Each the ANES and the GSS represent small sample sizes relative to sources

that pool over many surveys such as the SSRI data synthesis and the Huffington Post Pollster. The ANES and the GSS yield similar estimates, however, to Pew, which is based on a pooling of Pew's own surveys. All of these sources provide similar estimates of the proportion of adults who identify as Republican, between 23% and 25% as observed in the data synthesis. They provide somewhat lower estimates of the proportion who identify as Democrat (32%-33%) compared to 36% in the data synthesis; and higher estimates of those who identify with neither party (41%-45%) compared to 39% in the data synthesis.

American National Election Studies (2012).

General Social Survey (2015).

For Political Views, the SSRI data synthesis yields similar estimates of the percentage of US adults who identify as Liberal (24%), Conservative (39%), and Moderate (37%) as does a report based on a synthesis of data from Gallup (24%, 38% & 38%, respectively). The data synthesis also yields similar estimates to the large ( $n \sim 35,000$ ) nationally representative sample from the Pew Religious Landscape Survey (2014). Both the ANES and GSS estimates are somewhat

higher in the percentage of US adults who identify as Liberal. The ANES yields an estimate of of conservative that is substantially higher than all other sources.

In sum, there is variability across all sources in estimates of party identification and political ideology and no single sources provides a definitive estimate of the true underlying population total. The SSRI data synthesis, however, provides an estimate across the greatest range of data sources, including representative samples of surveys from Pew, Gallup, the ANES, the GSS, as well as other sources such as ABC and CBS news polls, the Annenburg National Election Survey, and other independent sources.
